ABSTRACT OF THE DISCLOSURE

When an engine unit of a printing apparatus issues a
calibration request, a controller unit of the printing
apparatus stores correction data in a storage unit. Upon
5   printing, a data controller checks if the correction data
is stored in the storage unit. If the correction data is
stored, the data controller forms a correction table on the
basis of the correction data. The data controller corrects
print data in accordance with the correction table, and
10   generates binary image data. The data controller then sends
the binary image data to the printing apparatus to make the
apparatus print.
